

Outlineoffungi.org - Note 553, [Uniappendiculata](#)

[Uniappendiculata](#) Tibpromma

[Uniappendiculata](#) is monotypic asexual genus represented by *U. kunmingensis* on dead stems of *Acer palmatum* in China. Phylogenetic analysis based on combined dataset of LSU, *tef1-α* and ITS sequences suggests that [Uniappendiculata](#) is a member of *Sulcatissporaceae* (*Pleosporales*, *Dothideomycetes*) and is related to *Pseudobambusicola* ([Wijayawardene et al. 2021](#)). On the other hand, characters of *U. kunmingensis*, such as acervular conidiomata surrounded by numerous black setae and subcylindrical, slightly curved, hyaline conidia with an appendage at both ends are extremely similar to those of *Pseudolachnella* (*Chaetosphaeriaceae*, *Chaetosphaeriales*, *Sordariomycetes*; [Hashimoto et al. 2015](#)). Considering that no genus with such asexual traits is known in *Sulcatissporaceae* ([Tanaka et al. 2015](#)) or even in *Dothideomycetes* ([Hongsanan et al. 2020](#)), additional materials including pure cultures and molecular evidences for *U. kunmingensis* are required to confirm phylogenetic validity of this intriguing genus.
